

Binding Simple Types to a Request (一)

- For simple types such as int, string, and double, ASP.NET Core automatically tries to bind the value to a route parameter, or a query string value:
 - If the parameter name matches a route parameter name, binds to the associated route value.
 - If the parameter name doesn't match any route parameter name, bind to a query string value.

70

Binding Simple Types to a Request (二)

■ Example

- /products/123
- /products?id=456

```
app.MapGet("/products/{id?}", (int id) => $"Received {id}");
```

71

Binding Simple Types to a Request (三)

- The [From*] attributes override ASP.NET Core's default logic and forces the parameters to load from a specific binding source.

72

Binding Complex Types to the JSON Body

- Minimal APIs can bind the body of a request to a single complex type by deserializing the request from JSON, create the object.

```
app.MapPost("/product", (Product product) => $"Received {product}");
record Product(int Id, string Name, int Stock);

{ "id": 1, "Name": "Shoes", "Stock": 12 }
```

1. ASP.NET Core MVC

Structure of ASP.NET Core

- ASP.NET Core is Microsoft's web development platform.
- Most of your development time will be spent with the application frameworks.

5

MVC Pattern (一)

- The MVC design pattern is a common pattern for designing apps that have UIs.

6

MVC Pattern (二)

■ Three components make up the MVC pattern:

- **Model**—The data that needs to be displayed.
- **View**—The template that displays the data provided by the model.
- **Controller**—Updates the model and provides the data for display to the view.

7

MVC Pattern (三)

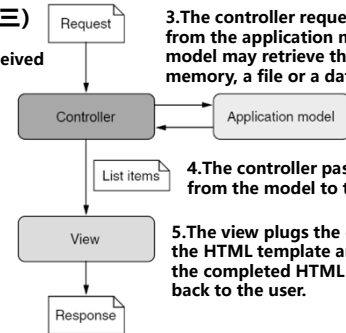

1. Request is received from a user.

2. The controller handles the request.

3. The controller requests data from the application model. The model may retrieve them from memory, a file or a database.

4. The controller pass the data from the model to the view.

5. The view plugs the data into the HTML template and sends the completed HTML page back to the user.

8

2. Configuring an ASP.NET Core MVC Application

You First Application

CodeLab 3.1

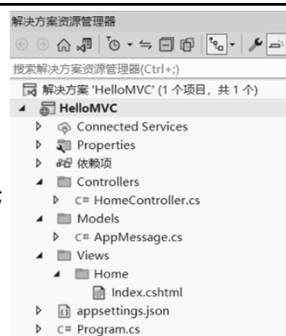

■ You are required to develop an application that receives a message from user and display it in the web page.

10

Project Structure

- The Program.cs file contains the code statements that are executed when the application is started.
- Configure the ASP.NET platform;
- Configure the individual frameworks it supports.

11

Services

- Services are objects that provide features in a web application.
- They are managed by the ASP.NET Core platform that can be shared by middleware components.

12

Configuration Service (一)

- Configuration is the set of external parameters provided to an application that controls the application's behavior in some way.
- It typically consists of a mixture of settings and secrets that the application loads at runtime.
 - A setting is value that changes the behavior of your application.
 - A secret is a special type of setting that contains sensitive data, such as a password.

13

Configuration Service (二)

- One of the built-in features is access to the application's configuration settings, which is presented as a service.
- The main source of configuration data is the **appsettings.json** file.

14

Configuration Service (三)

- The configuration service will process the JSON configuration file and create nested configuration sections.

15

Configuration Service (四)

- Most projects contain more than one JSON configuration file, allowing different settings to be defined for different parts of the development cycle.
 - Development
 - Staging
 - Production

16

Launch Settings

- The launchSettings.json file contains the configuration settings for starting the ASP.NET Core platform:
 - The TCP ports that are used to listen for HTTP and HTTPS requests;
 - The environment used to select the additional JSON configuration files.
